

Which syndrome features matter for epicenter localization?

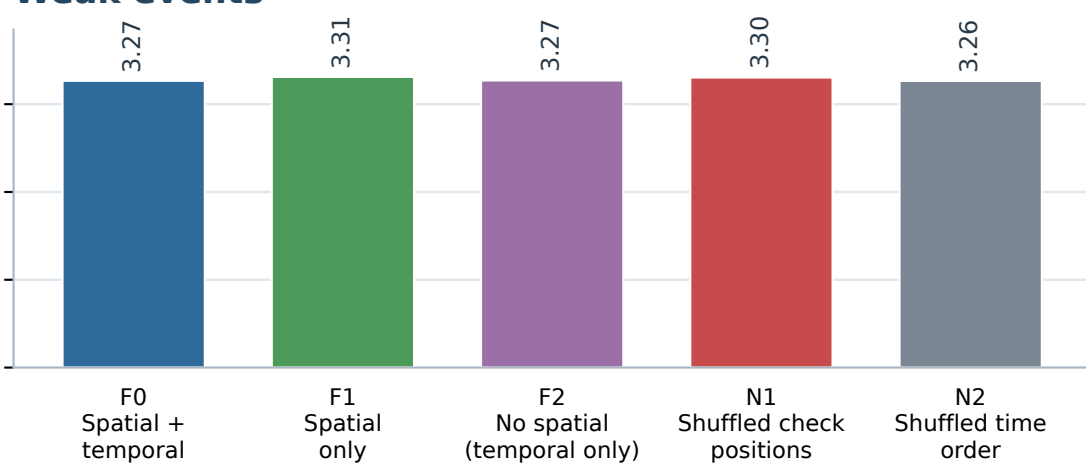

Feature ablation on the primary SVR corpus (d5, 4.096 ms, fixed model and split)

Lower mean localization error is better. Only the five poster-relevant controls are shown.

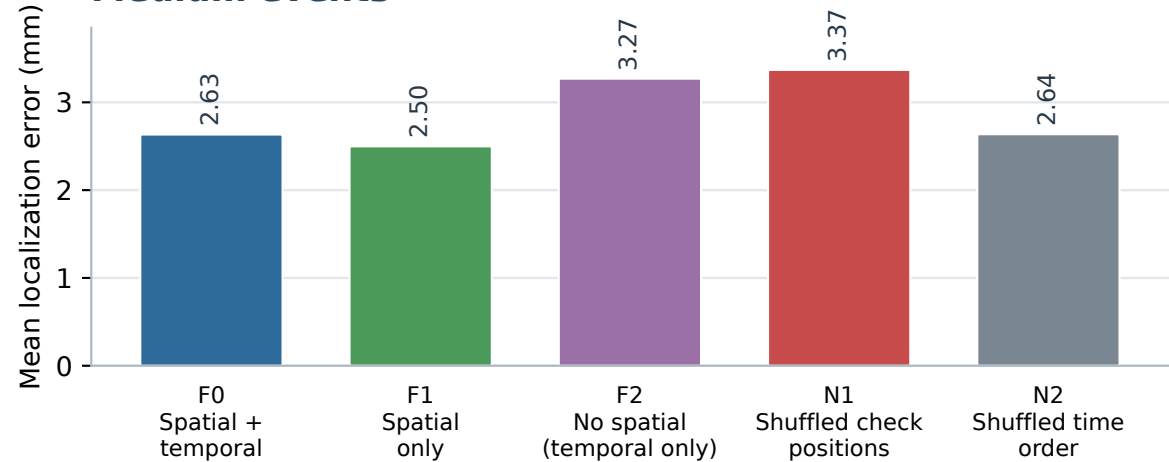

All events

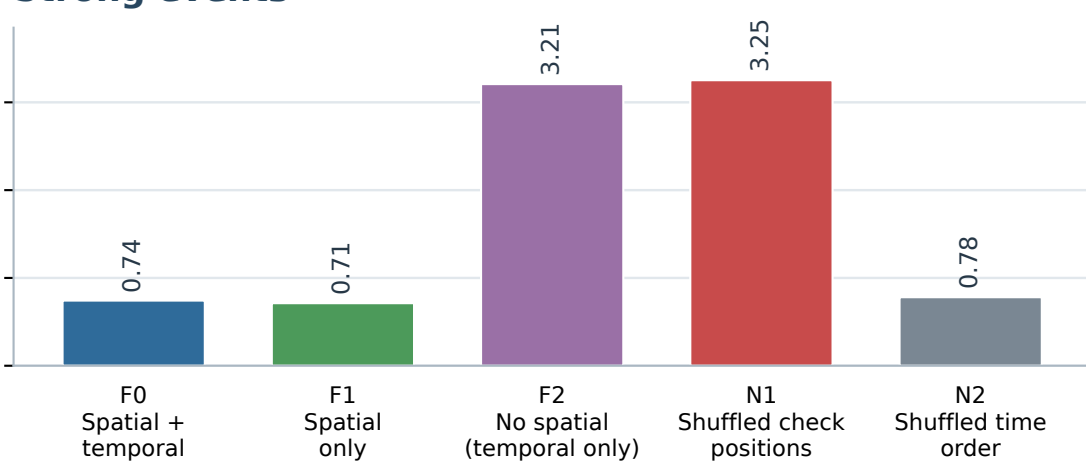

Weak events

Medium events

Strong events

Interpretation: removing spatial check information (F2) causes a large error increase; shuffling check positions (N1) has a similar effect.

F0 = spatial + temporal | F1 = spatial only | F2 = no spatial / temporal only | N1 = shuffled check positions | N2 = shuffled time order

All variants use the same 120-dimensional input size and fixed SVR hyperparameters; no test-set feature selection was performed.
